Abstract-The absorption spectra in transition metal ions involving d-d transitions have been used for following the kinetics of the chemical reaction leading to the development of the mechanism of chemical and biochemical reactions. The 4f-4f transition spectral intensity changes have very rarely been used for mechanistic and kinetic investigations. Thus, it has been considered quite interesting to explore the interaction of Pr³⁺ with biomolecules in presence of Ca²⁺ by employing absorption spectral research owing to the ease of Ln³⁺ ions to act as surrogates for Ca²⁺ ions.

The kinetics for the complexation of Pr(III): Amino acid with Ca(II) have been investigated in DMF medium at different temperatures viz., 298K, 303K, 308K, 313K and 318K. Three amino acids viz., Glycine, L-Alanine and L-Phenylalanine were selected for the kinetic study of the complexation reactions of Ln(III) ion and amino acid ligands in the presence of Ca(II) ion. From the values of the rate of reaction at different temperatures, the activation energy (E_a) of the various complexes are determined and from the calculated data of activation energies, thermodynamic parameters like ΔH° , ΔS° and ΔG° of the formation of complexes are evaluated. The determined activation energy parameters corresponding to the rate constants and thermodynamic parameters corresponding to the formation of the complexes of Pr(III): Amino acid: Ca(II) were found to be highly favourable.

Keywords- 4f-4f Transition; Absorption Spectral Studies; Kinetics; Activation Energy; Thermodynamic Parameters

I. INTRODUCTION

In lanthanides, rarely absorption spectra, involving 4f-4f transitions are used for mechanistic studies of the kinetic reactions involving lanthanide ions and coordinating ligands like biomolecules. The close resemblance between most abundant and biologically important Ca(II) ion and paramagnetic lanthanides(III) ions, in coordination and binding characteristics [1, 2], allow lanthanide(III) ion to act as an “absorption spectral probe” in understanding biochemical reactions and functions involving isomorphous Ca(II) ion substitution by Ln(III) [3-5].

In the previous work [6-7], the absorption difference and comparative absorption spectroscopy involving 4f-4f transitions of the heterobimetallic complexation of some selected amino acids with Pr(III) and Ca(II) was carried out in aqueous and different aquated organic solvents. The difference in the energy parameters like Slator Condon (F_K), and Lande Spin-orbit Coupling (ζ_{4f}), Nephelauxetic ratio (β), bonding parameter ($b^{1/2}$) and percent covalency (δ) are calculated to explain the nature of complexation. The changes in the values of experimentally calculated oscillator strengths (P) and Judd–Ofelt electric dipole intensity parameter, T_λ ($\lambda = 2, 4, 6$) suggest the specific correlation between relative intensities, ligand structures and nature of complexation. The variation of intensities (oscillator strengths) of 4f-4f bands during hydrolysis, as well as the variation of Judd–Ofelt intensity parameters has helped in following the preliminary kinetic studies of hydrolysis. The kinetics for the formation of Pr(III): Amino acids: Ca(II) complex is evaluated at different temperatures in DMF medium. From the rates of reactions at different temperatures, the values of activation energy (E_a) of the formation of the complexes are evaluated.

II. EXPERIMENTAL

A. Materials

Praseodymium(III) nitrate of 99% purity, purchased from CDH, Mumbai and Amino acids viz; Glycine, L-Alanine and L-Phenylalanine from SRL Pvt. Ltd., Mumbai, are used for the present analysis. Solvent used is Dimethylformamide(DMF) since it showed maximum intensification among other organic solvents analysed [6-7].

B. Methods

The rates of the complexation of Pr³⁺: Amino acid with Ca²⁺ have been measured applying two different methods i.e., comparative absorption and absorption difference spectroscopy using 4f-4f transitions by monitoring the changes of absorbance and oscillator strength of multiplet to multiplet electronic transitions of Pr³⁺ ion. The activation energy of the complexation of Pr³⁺: Amino acid with Ca²⁺ has been explored from the data of rates at different temperatures by following

Arrhenius equation. The thermodynamic parameters for the complexation of Pr³⁺: Amino acid: Ca²⁺ ion is calculated using Vant Hoff's plot of log k against 1/T.

The calculation of the band intensities is based upon the theoretical treatment derived by Judd [8] and Ofelt [9]. They considered that the transitions are essentially electric dipole in character and the oscillator strength corresponding to the induced electric dipole transition $\Psi J \rightarrow \Psi' J'$ as given by

$$P = \sum_{\lambda=2,4,6} T_{\lambda} \sigma(f^n \Psi J \| U^{(\lambda)} \| f^n \Psi' J')^2 \quad (1)$$

where $U^{(\lambda)}$ is matrix element of rank λ . The three quantities T_2 , T_4 and T_6 are related to the radial parts of the $4f^N$ wave functions which are the wave functions of the perturbing configurations of the nearest $4f^{n-1} 5d$.

The measured intensity of an absorption band is related to the probability (P) for the absorption of radiant energy (oscillator strength) by the expression:

$$P = 2303 mc^2 / N\pi e^2 \int \epsilon_i(\sigma) d\sigma \quad (2)$$

or $P = 4.318 \times 10^{-9} \int \epsilon_i(\sigma) d\sigma$

where ϵ is the molar absorptivity at the energy σ (cm^{-1}) and other symbols have their usual significance. From these values of T_2 , T_4 and T_6 are calculated applying

$$\frac{P_{\text{obs}}}{V} = [(U^2)]^2 T_2 + [(U^4)]^2 T_4 + [(U^6)]^2 T_6 \quad (3)$$

where $U^{(\lambda)}$ are the matrix elements of Pr³⁺ and Nd³⁺ system given by Carnall [10]. The activation energy for the complexation of Pr³⁺/Nd³⁺: Amino acid in DMF is calculated from the plot of log k (k= rate constant) against 1/T by using Arrhenius rate equation [11].

$$\log k = \log A - \frac{E_a}{2.303R} \times \frac{1}{T} \quad (4)$$

where A is the pre-exponential factor or frequency factor. From the slope the activation energy (E_a) is calculated as:

$$E_a = \text{Slope} \times 2.303 \times R \quad (5)$$

where R is the universal gas constant.

The thermodynamic parameters for the complexation of Pr³⁺: Amino acid and Ca²⁺ ion is evaluated using Van't Hoff plot [12] of log k against 1/T.

$$\ln k = -\frac{\Delta H^0}{R} \left[\frac{1}{T} \right] + \frac{\Delta S^0}{R} \quad (6)$$

or $\ln k = -\frac{\Delta G^0}{RT}$

III. RESULTS AND DISCUSSIONS

Figs. 1-2 show the time span absorption spectra of the formation of Pr(III): L-Alanine with Ca(II) at 298K and 303K respectively.

It can be seen that there is an increase of absorbance and intensity with time. Both hypersensitive and pseudo-hypersensitive transitions of Pr(III) display significant changes during complexation, which can be seen from the spectral changes with time. The same trend was observed for Pr(III): Glycine/L-Phenylalanine: Ca(II) at different temperatures:- 298K, 303K, 308K, 313K and 318K. On the other hand it was found that the bands other than hypersensitive bands can acquire sensitivity due to the binding characteristics of the coordinating ligands, change in denticity, nature of the donor sites as well as nature of Ln(III)- Ligand bond and nature of complex species, which have induced significant intensity to the non-hypersensitive $4f-4f$ bands. Such transitions are known as pseudo-hypersensitive transitions [13-15]. Judd marked the hypersensitivity as due to the changes in symmetry of the environment of a lanthanide ion. Therefore, it has been suggested

that the changes in the oscillator strengths of both hypersensitive and non-hypersensitive transitions should be considered for spectral structure correlation in Ln(III) complexes with coordination ligands including biomolecules.

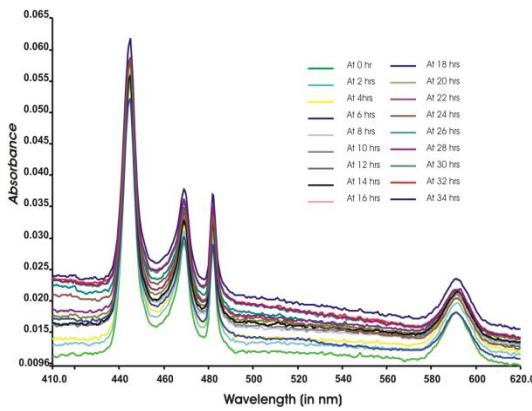

Fig. 1 Absorption Spectra of Pr(III): L-Alanine complexation with Ca(II) at different hours at 298K (25 °C)

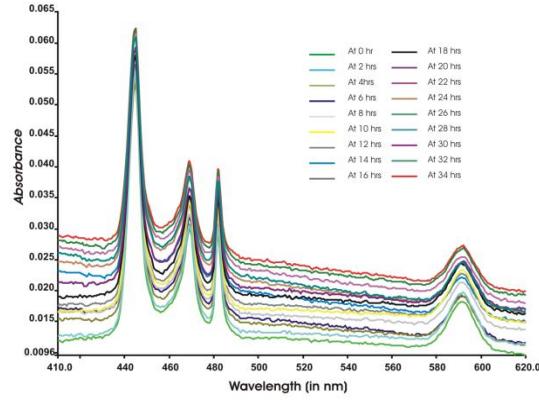

Fig. 2 Absorption Spectra of Pr(III): L-Alanine complexation with Ca(II) at different hours at 303K (300 °C)

Tables 1-5 show the observed (P_{obs}) and calculated (P_{cal}) values of oscillator strengths Judd-Ofelt intensity parameter, T_λ ($\lambda = 2, 4, 6$) for complexation of Pr(III): L Alanine with Ca(II) in DMF at different temperatures, viz; 298K, 303K, 308K, 313K and 318K.

The rate constants for the complexation at different temperatures were evaluated from the plots of oscillator strength versus time for Pr(III): Amino acid: Ca(II) complexation. From Tables 6-8, it can be clearly seen that the rates of complexation of Pr(III): Amino acid with Ca(II) linearly increases with the increase in time.

Since the intensity of 4f-4f transitions show a substantial increase with Time, hence absorption spectral analysis of 4f-4f transitions can be used to explore the kinetics of the formation of the complexes. The observed values of rate (k) have been evaluated in terms of the complex formed during the progress of the reaction and the same has been evaluated from the plots of oscillator strength of $^3\text{H}_1 \rightarrow ^3\text{P}_2$ transition of Pr(III) complex formation versus time (in hour). The values of activation energy (E_a) and thermodynamic parameters are evaluated from the Van't Hoff plot of log k against 1/T (Fig. 3).

Fig. 3 Vant Hoff's plot of $\log k$ vrs $1/T$ for (a) Glycine,(b)L-Alanine and (c) L-Phenylalanine

This technique can provide a means to determine indirectly the thermodynamic parameters of the complexation of Pr(III) and Ca^{2+} ions in DMF medium. It was clearly seen that the rate of complexation increases with increase in temperature and from which the activation energy E_a of the complexation is evaluated and consequently other thermodynamic parameters have been evaluated. The thermodynamic values are given in Table 9.

IV. CONCLUSIONS

From the values of the thermodynamic parameters, it was found that:

The values of ΔH^0 and ΔS^0 are positive which indicates that the complexation reaction is endothermic and entropy increasing process.

Further, since $T\Delta S^0 > \Delta H^0$ the coordination reaction is entropy driven process. Negative values of ΔG^0 predict that the complex formation is favourable and is spontaneous. The same trend was seen in all the complexes of Pr(III) with Glycine/ L-Alanine/ L-Phenylalanine in the presence of Ca(II).

Thus, it can be further justified that the simultaneous complexation reactions between Pr(III) ions with amino acids and metal ions, Ca(II) occur but at a spontaneous pace, following the randomness of the system when it approaches higher temperatures (increasing ΔS^0 values).

Further, from the Tables 6, 7, 8 it has been found that the activation energies (E_a) for L-Alanine in Pr(III) systems was the lowest i.e. 0.00319 KJ, which supports the earlier report that the most sensitive ligand (amino acid) in binding with Pr(III) was L-Alanine, which was followed by Glycine and the least sensitive was L-Phenylalanine.

The lower values of E_a substantiate further evidence that the reaction is a fast one.

ACKNOWLEDGEMENTS

The authors are thankful for the Department of Chemistry, Nagaland University and the Department of Chemistry, Manipur University to carry out this research work.
